

The vulva is the external part of the female reproductive system, and it has a unique shape that can vary from person to person. Before puberty, the vulva may be smaller and less developed than it will be after puberty.

Generally, the vulva includes several parts:

- **Labia Majora:** These are the outer lips of the vulva. They are usually fleshy and can be slightly more prominent in some individuals.
- **Labia Minora:** These are the inner lips that are located just inside the labia majora. They tend to be thinner and more delicate; before puberty, they might not be very prominent.
- **Clitoris:** This is a small, sensitive organ located at the top of the vulva, partially covered by a fold of skin (the clitoral hood). It is usually small and less developed before puberty.
- **Urethral Opening:** This is the opening where urine exits the body, located below the clitoris.
- **Vaginal Opening:** This is the entrance to the vagina, located beneath the urethral opening.

In summary, the vulva before puberty is typically smaller and less defined, as the body is still developing. It's important to remember that everyone's body is different, and there's a wide range of shapes and sizes that are all perfectly normal.
