

How Do Eagles Build Their Nests?

Did you know that eagles are amazing builders? They have special places where they like to make their homes, called nests. One interesting place that eagles often build their nests is in rock crevices.

What Are Rock Crevices?

First, let's talk about what a rock crevice is. A rock crevice is a small opening or crack in a rock. It's like a little space between two big rocks. These spaces can be high up on cliffs or mountains. They provide a safe and secure place for eagles to lay their eggs and raise their young.

Why Do Eagles Choose Rock Crevices?

Eagles choose rock crevices for a few important reasons:

- **Safety:** Being high up in the rocks keeps them away from many predators (animals that might want to eat them or their babies).
- **Protection:** The walls of the rock crevice protect the eggs and baby eagles from bad weather, like rain and strong winds.
- **Good Spot for Hunting:** Being up high helps eagles see better so they can spot food, like fish or small animals, to eat.

What Do Eagles Use to Build Their Nests?

Eagles are very skilled at gathering materials for their nests. They use:

- Branches
- Grass
- Feathers
- Other soft things to keep their nests comfortable

Sometimes, they can even use items people drop, like pieces of fabric or plastic!

How Do Eagles Raise Their Young?

Once the eagle has built a nest in a rock crevice, the female eagle lays eggs inside. Both mom and dad eagles take turns sitting on the eggs to keep them warm.

When the baby eagles (called eaglets) hatch, the parents work hard to bring them food and keep them safe until they are big enough to fly away and hunt for themselves.

Conclusion

Eagles are incredible birds that choose clever places to build their nests, like rock crevices. This helps keep their babies safe and gives them a great view to find food. Isn't that fascinating?
